The following is intended to outline our general product direction. It is intended for information purposes only, and may not be incorporated into any contract. It is not a commitment to deliver any material, code, or functionality, and should not be relied upon in making purchasing decisions. The development, release, and timing of any features or functionality described for Oracle’s products remains at the sole discretion of Oracle.
INTRODUCTION

Naming method resolves names to a connect descriptor. One of the naming methods is directory-naming method. Directory naming resolves a database service name, Net service name or Net service alias stored in a centralized LDAP-compliant directory server, including Oracle Internet Directory and Microsoft Active Directory. Centralized administration of database services and Net service names makes them easier to add or relocate. Users initiate a connection request by providing a connect string. A connect string includes a username and password, along with a connect identifier. A connect identifier can be the connect descriptor itself or a name that resolves to a connect descriptor.

This paper outlines detailed steps to configure Active Directory 2003 for supporting net service naming.

STEPS TO CONFIGURE ACTIVE DIRECTORY 2003

Active Directory has to be configured for oracle usage in order to use functionality provided by directory naming. This involves extending active directory schema objects and creating OracleContext container. Oracle Schema objects are sets of rules for Oracle Net Services and Oracle Database entries and their attributes stored in Active Directory. Active Directory name resolution provides central administration of database services and net service names, making it easier to add or relocate services leveraging existing windows environment in an enterprise.

Oracle Net naming with Active Directory is supported from Windows hosts. Services (database) can be running on any machine, and do not necessarily have to be Windows hosts.

After promoting Windows Server 2003 to become an Active Directory domain controller, Active Directory must be configured to allow an Oracle Context to be created.

Log on to the Active Directory server with Administrative privilege.
ADSI Edit is required to perform this activity. ADSI Edit Microsoft Management Console snap-in is available as part of the Windows 2003 Support Tools located on the Windows Server 2003 media:

Z:\SUPPORT\TOOLS\SUPTOOLS.MSI.

See Also:

Following are the main steps to configure Active Directory 2003 for Net Naming:

° Allow schema update
° Enable anonymous browsing of Active Directory
° Create Oracle Context with NetCA

Allowing Schema Update

Caution:

Active Directory Schema extensions are permanent - attributes and object classes, such as those created as part of OracleContext creation, cannot be removed.

Taking a system/catalog backup prior to creating the OracleContext is highly recommended.

Having granted Schema write privileges, Active Directory must still then be explicitly configured to allow Schema modification. This is achieved by adding a registry parameter, which is as follows:

1. Click Start.
2. Click Run.
3. Enter regedit.
4. Click OK.
5. Navigate to registry subkey:
   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NTDS\Parameters
6. Add new parameter Schema Update Allowed (of type REG_DWORD) with a hexadecimal value of 1.
This setting is dynamic and takes immediate effect.

**Enable anonymous browsing**

Windows Server 2003 Active Directory allows only authenticated users to initiate an LDAP request against Windows Server 2003-based domain controllers. An LDAP browser/modifier is required to enable anonymous browsing. An easy way to modify required attribute values is to use the Windows ADSI Edit utility.

To invoke ADSI Edit, in the MMC Console Root, click File, Add/Remove Snap-in, Add, select ADSI Edit, click Add, Close, then click OK. Select, then right-click ADSI Edit, click Connect to, select Configuration Naming Context, then click OK.

Explode the Configuration container and navigate to:

Configuration [acme.com]

- CN=Configuration, DC=ACME, DC=COM
- CN=Services
- CN=Windows NT
- CN=Directory Service

Right-click the CN=Directory Service container, select Properties, then scroll down to select the dSHeuristics attribute.

Edit the dSHeuristics attribute and set its value to 0000002. Setting this value allows anonymous clients to perform any operation that is permitted by the access control list (ACL).

The requirement to enable anonymous browsing has been removed as part of the fix for bug 6639240.

**Extending Schema and Creating Oracle Context**

You must create an Oracle Context to use Net directory naming features with Active Directory. Oracle Context is the top-level Oracle entry in the Active Directory tree. It contains Oracle Database service and Oracle Net service name object information.

Use Oracle Net Configuration Assistant (NetCA) to extend the schema and create your Oracle Context. Oracle NetCA is a graphical, wizard-based tool used to configure and manage Oracle Network configurations. You can create the Oracle Context during or after Oracle Database Custom installation.

You can create only one Oracle Context for each Windows 2000 or Windows 2003 domain (administrative context). You must have the right to create domain and enterprise objects in order to create the Oracle Context in Active Directory with Oracle Net Configuration Assistant.
1. Run the Network Configuration Assistant (NetCA):
   a) Click Start, and then click All Programs.
   b) Click Oracle, Configuration and Migration Tools, then Net Configuration Assistant.
2. Select the Directory Usage Configuration radio button, and then click next.
3. Select Directory Type Microsoft Active Directory, and then click next.
   Note: The Microsoft Active Directory configuration option is only available in the Windows version of NetCA.
4. Select the option to configure the directory for Oracle usage and create the Oracle Schema and Context, then click next.
5. Enter the Active Directory hostname, and then click next.
6. Select the option to upgrade the Oracle Schema, and then click next.
7. The next page should denote successful Directory configuration:
   Directory usage configuration complete!
   Example: The distinguished name of your default Oracle Context is:
   Cn=OracleContext, DC=ACME, DC=COM
8. Click next, then click Finish.

The following restrictions apply to creating Oracle schema objects to use with Active Directory:

Only one Oracle schema object can be created for each forest.

The Windows 2000 or Windows 2003 domain controller must be the operations master that allows schema updates. See your operating system documentation for instructions.

If the Active Directory display is not configured to accept all 24-default languages, then Oracle schema object creation can fail while Oracle Net Configuration Assistant is configuring Active Directory as the directory server. Before running Oracle Net Configuration Assistant to complete directory access configuration, verify that the display specifiers for all 24 languages are populated by entering the following at the command prompt:

```
ldifde -p OneLevel -d cn=DisplaySpecifiers, cn=Configuration, domain context -f temp file
```

where:

*domain context* is the domain context for this Active Directory server. For example, *dc=example, dc=com*

*temp file* is a file where you want to put the output.
If the command reports that fewer than 24 entries were found, then you can still use Oracle Net Configuration Assistant. However, the report will indicate that Oracle schema object creation failed, rather than simply reporting that display specifiers for some languages were not created.

Display Specifiers Not Created

When Net Configuration Assistant creates the Oracle schema object in Active Directory, the display specifiers for Oracle entries are not created. This means you cannot view Oracle database entries in Active Directory interfaces.

You can manually add these entries into Active Directory after the Oracle schema object has been created by doing the following, using the same Windows user identification you used when creating the Oracle schema object with Net Configuration Assistant:

Open a command shell.

Change directory to ORACLE_HOME\ldap\schema\ad.

Copy `adDisplaySpecifiers_us.sbs` to `adDisplaySpecifiers_us.ldif`.

Copy `adDisplaySpecifiers_other.sbs` to `adDisplaySpecifiers_other.ldif`.

Edit each of these ldif files, replacing all occurrences of `%s_AdDomainDN%` with the domain DN for the specific Active Directory into which you want to load the display specifiers (for example, `dc=acme, dc=com`).

Run the following commands:

```
ldapmodify -h <ad hostname> -Z -f adDisplaySpecifiers_us.ldif
ldapmodify -h <ad hostname> -Z -f adDisplaySpecifiers_other.ldif
```

where `<ad hostname>` is the hostname of the Active Directory domain controller to which you want to load the display specifiers.

Successful completion of OracleContext enables Active Directory to store NetServices and DatabaseServices. NetManager or Oracle Enterprise Manager can be used to create service names in active directory.

Default access control lists (ACLs) on NetServices names does not allow anonymous reading of its attributes. If the oracle client binds anonymously for name resolution then ACLs on OracleContext and Net Service names should be changed to allow anonymous reading. In Oracle Database 11g, Database administrators can restrict access to a service by configuring oracle clients to authenticate and control the services available to them by ACLs on services. Use the `NAMES.LDAP_AUTHENTICATE_BIND=TRUE` parameter in sqlnet.ora to specify whether the LDAP naming adapter should attempt to authenticate when it
connects to the Active directory to resolve the name in the connect string. Windows client uses native authentication method to authenticate to Active Directory.

RELATED BUGS
The following bugs have been encountered and fixed recently. These fixes may not be required for every usage scenario, however they are listed here for completeness:

2. Bug 7145872 – fixes a crash in NetCA on Win64 platform while configuring Active Directory.

CONCLUSION
Windows Server 2003 Active Directory allows only authenticated users can initiate an LDAP request against Windows Server 2003-based domain controllers. Updating registry entry, one attribute of active directory helps in successful completion NetCA directory configuration thus enabling it for Oracle Net Naming.
